ASSIGNMENT-3

1. Counting Elements Given an integer array arr, count how many elements x there are, such that x + 1 is also in arr. If there are duplicates in arr, count them separately. Example Input: arr = [1,2,3] Output: 2 Explanation: 1 and 2 are counted cause 2 and 3 are in arr. Example 2: Input: arr = [1,1,3,3,5,5,7,7] Output: 0 Explanation: No numbers are counted, cause there is no 2, 4, 6, or 8 in arr. Constraints: • 1 <= arr.length <= $1000 \cdot 0$ <= arr[i] <= $1000 \cdot 0$ def count elements(arr):

```
def count_elements(arr):
    element_set = set(arr)
    count = 0
    for x in arr:
        if x + 1 in element_set:
            count += 1
        return count
# Test cases
print(count_elements([1, 2, 3])) # Output: 2
print(count_elements([1, 1, 3, 3, 5, 5, 7, 7]))
```

2. Perform String Shifts You are given a string s containing lowercase English letters, and a matrix shift, where shift[i] = [directioni, amounti]: ● directioni can be 0 (for left shift) or 1 (for right shift). ● amounti is the amount by which string s is to be shifted. ● A left shift by 1 means remove the first character of s and append it to the end. ● Similarly, a right shift by 1 means remove the last character of s and add it to the beginning. Return the final string after all operations. Example 1: Input: s = "abc", shift = [[0,1],[1,2]]

```
File Edit Format Run Options Window Help
def string shift(s, shift):
    net shift = 0
    for direction, amount in shift:
        if direction == 0:
            net shift -= amount
        else:
            net shift += amount
    net shift %= len(s)
    return s[-net_shift:] + s[:-net shift] if net shift != 0 else s
# Test cases
print(string_shift("abc", [[0, 1], [1, 2]])) # Output: "cab"
print(string shift("abcdefg", [[1, 1], [1, 1], [0, 2], [1, 3]])) # Out
OUTPUT:
 = RESTART: C:/Users/q
 cab
 efgabcd
```

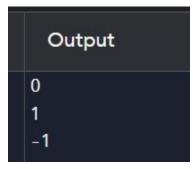

3. Leftmost Column with at Least a One A row-sorted binary matrix means that all elements are 0 or 1 and each row of the matrix is sorted in non-decreasing order. Given a row-sorted binary matrix binaryMatrix, return the index (0-indexed) of the leftmost column with a 1 in it. If such an index does not exist, return -1. You can't access the Binary Matrix directly. You may only access the matrix using a BinaryMatrix interface: • BinaryMatrix.get(row, col) returns the element of the matrix at index (row, col) (0-indexed). • BinaryMatrix.dimensions() returns the dimensions of the matrix as a list of 2 elements [rows, cols], which means the matrix is rows x cols. Submissions making more than 1000 calls to BinaryMatrix.get will be judged Wrong Answer. Also, any solutions that attempt to circumvent the judge will result in disqualification. For custom testing purposes, the input will be the entire binary matrix mat. You will not have access to the binary matrix directly. Example 1: Input: mat = [[0,0],[1,1]] Output: 0 Example 2: Input: mat = [[0,0],[0,1]] Output: 1 Example 3: Input: mat = [[0,0],[0,0]] Output: -1 Constraints: • rows == mat.length • cols == mat[i].length • 1 <= rows, cols <= 100 • mat[i][j] is either 0 or 1. • mat[i] is sorted in non-decreasing order. class BinaryMatrix: def __init__(self, mat):

```
self.mat = mat self.call count = 0
```

```
def dimensions(self):
    return [len(self.mat), len(self.mat[0])]

def leftmost_column_with_one(binaryMatrix):
    rows, cols = binaryMatrix.dimensions()
    current_row, current_col = 0, cols - 1
    leftmost = -1
    while current_row < rows and current_col >= 0:
        if binaryMatrix.get(current_row, current_col) == 1:
            leftmost = current_col
            current_col -= 1
        else:
            current_row += 1
    return leftmost
# Test cases
```

print(leftmost column with one(BinaryMatrix([[0, 0], [1, 1]]))) # Outp

File Edit Format Run Options Window Help

4. First Unique Number You have a queue of integers, you need to retrieve the first unique integer in the queue. Implement the FirstUnique class: ● FirstUnique(int[] nums) Initializes the object with the numbers in the queue. ● int showFirstUnique() returns the value of the first unique integer of the queue, and returns -1 if there is no such integer. ● void add(int value) insert value to the queue. Example 1: Input: ["FirstUnique","showFirstUnique","add","showFirstUnique","add","showFirstUnique","add","showFirstUnique","add","showFirstUnique","add","showFirstUnique"] [[[2,3,5]],[],[5],[],[3],[]] Output: [null,2,null,2,null,3,null,-1] Explanation:

```
ew.py - C:/Users/gowth/AppData/Local/Programs/Python/Python312/ew.py (3.12.2)
File Edit Format Run Options Window Help
from collections import deque, Counter
class FirstUnique:
    def init (self, nums):
        self.queue = deque(nums)
        self.count = Counter(nums)
    def showFirstUnique(self):
        while self.queue and self.count[self.queue[0]] > 1:
             self.queue.popleft()
        return self.queue[0] if self.queue else -1
    def add(self, value):
        self.queue.append(value)
        self.count[value] += 1
# Test cases
firstUnique = FirstUnique([2, 3, 5])
print(firstUnique.showFirstUnique())
                                        # Output: 2
firstUnique.add(5)
print(firstUnique.showFirstUnique()) # Output: 2
firstUnique.add(2)
print(firstUnique.showFirstUnique()) # Output: 3
firstUnique.add(3)
print(firstUnique.showFirstUnique()) # Output: -1
```

Output
2
2
3
-1
-1
17
809
-1

5. Check If a String Is a Valid Sequence from Root to Leaves Path in a Binary Tree Given a binary tree where each path going from the root to any leaf form a valid sequence, check if a given string is a valid sequence in such binary tree. We get the given string from the concatenation of an array of integers arr and the concatenation of all values of the nodes along a path results in a sequence in the given binary tree. Example 1: Input: root = [0,1,0,0,1,0,null,null,1,0,0], arr = [0,1,0,1] Output: true Explanation: The

path $0 \rightarrow 1 \rightarrow 0 \rightarrow 1$ is a valid sequence (green color in the figure). Other valid sequences are: $0 \rightarrow 1 \rightarrow 1 \rightarrow 0$ $0 \rightarrow 0 \rightarrow 0$ Example 2: Input: root = [0,1,0,0,1,0,null,null,1,0,0], arr = [0,0,1] Output: false Explanation:

```
class TreeNode:
   def __init__(self, val=0, left=None, right=None):
        self.val = val
       self.left = left
       self.right = right
def is valid sequence(root, arr):
   def dfs(node, arr, index):
       if not node or index >= len(arr) or node.val != arr[index]:
           return False
       if not node.left and not node.right and index == len(arr) - 1:
            return True
       return dfs (node.left, arr, index + 1) or dfs (node.right, arr, i
   return dfs(root, arr, 0)
# Test cases
root = TreeNode(0, TreeNode(1, TreeNode(0, None, TreeNode(1)), TreeNode
print(is valid sequence(root, [0, 1, 0, 1])) # Output: True
print(is valid sequence(root, [0, 0, 1])) # Output: False
print(is valid sequence(root, [0, 1, 1])) # Output: False
OUTOUT:
   ==== RESTART: (
   True
```

6. Kids With the Greatest Number of Candies There are n kids with candies. You are given an integer array candies, where each candies[i] represents the number of candies the ith kid has, and an integer extraCandies, denoting the number of extra candies that you have. Return a boolean array result of length n, where result[i] is true if, after giving the ith kid all the extraCandies, they will have the greatest number of candies among all the kids, or false otherwise. Note that multiple kids can have the greatest number of candies. Example 1: Input: candies = [2,3,5,1,3], extraCandies =

False False

>

```
file Edit Format Run Options Window Help

def kids_with_candies(candies, extraCandies):
    max_candies = max(candies)
    return [candy + extraCandies >= max_candies for candy in candies]

# Test cases
print(kids_with_candies([2, 3, 5, 1, 3], 3)) # Output: [True, True, True,
```

Output [True, True, True, False, True]

7.Max Difference You Can Get From Changing an Integer You are given an integer num. You will apply the following steps exactly two times: \bullet Pick a digit x (0 <= x <= 9). \bullet Pick another digit y (0 <= y <= 9). The digit y can be equal to x. \bullet Replace all the occurrences of x in the decimal representation of num by y. \bullet The new integer cannot have any leading zeros, also the new integer cannot be 0. Let a and b be the results of applying the operations to num the first and second times, respectively. Return the max difference between a and b. Example 1: Input: num = 555 Output: 888 Explanation: The first time pick x = 5 and y = 9 and store the new integer in a. The second time pick x = 5 and y = 1 and store the new integer in b. We have now a = 999 and b = 111 and max difference = 888 Example 2: Input: num = 9 Output: 8 Explanation: The first time pick x = 9 and y = 9 and store the new integer in a. The second time pick x = 9 and y = 1 and store the new integer in b. We have now a = 9 and b = 1 and max difference = 8

```
File Edit Format Run Options Window Help
def max diff(num):
    s = str(num)
    a = s
    b = s
    for digit in s:
        if digit != '9':
            a = s.replace(digit, '9')
            break
    for digit in s:
        if digit != '1':
            b = s.replace(digit, '0' if digit == s[0] else '1')
            break
    return int(a) - int(b)
# Test cases
print(max diff(555)) # Output: 888
print(max diff(9)) # Output: 8
```

```
Output

888
8
820000
800000
```

8. Check If a String Can Break Another String Given two strings: s1 and s2 with the same size, check if some permutation of string s1 can break some permutation of string s2 or vice-versa. In other words s2 can break s1 or vice-versa. A string x can break string y (both of size n) if x[i] >= y[i] (in alphabetical order) for all i between 0 and n-1. Example 1: Input: s1 = "abc", s2 = "xya" Output: true Explanation: "ayx" is a permutation of s2="xya" which can break to string "abc" which is a permutation of s1="abc". Example 2: Input: s1 = "abe", s2 = "acd".

```
File Edit Format Run Options Window Help

def check_if_can_break(s1, s2):
    s1, s2 = sorted(s1), sorted(s2)
    return all(c1 >= c2 for c1, c2 in zip(s1, s2)) or all(c2 >= c1 for

# Test cases
print(check_if_can_break("abc", "xya")) # Output: True
print(check_if_can_break("abe", "acd")) # Output: False
print(check_if_can_break("leetcodee", "interview")) # Output: True

Output

True
False
True
```

9. Number of Ways to Wear Different Hats to Each Other There are n people and 40 types of hats labeled from 1 to 40. Given a 2D integer array hats, where hats[i] is a list of all hats preferred by the ith person. Return the number of ways that the n people wear different hats to each other. Since the answer may be too large, return it modulo 109 + 7. Example 1: Input: hats = [[3,4],[4,5],[5]] Output: 1 Explanation: There is only one way to choose hats given the conditions. First person choose hat 3, Second person choose hat 4 and last one hat 5. Example 2: Input: hats = [[3,5,1],[3,5]]

```
File Edit Format Run Options Window Help
def number ways (hats):
    from collections import defaultdict
    dp = defaultdict(int)
    dp[0] = 1
    all mask = (1 << len(hats)) - 1
    hat_to_people = defaultdict(list)
    for i, hat list in enumerate(hats):
         for hat in hat list:
             hat to people[hat].append(i)
    for hat in range(1, 41):
         new_dp = dp.copy()
         for mask, ways in dp.items():
             for person in hat to people[hat]:
                  if mask & (1 << person) == 0:</pre>
                      new dp[mask \mid (1 << person)] = (new <math>dp[mask \mid (1 << person)] + ways) % MOD
         dp = new dp
    return dp[all_mask]
# Test cases
print(number_ways([[3, 4], [4, 5], [5]])) # Output: 1
print(number_ways([[3, 5, 1], [3, 5]])) # Output: 4
print(number_ways([[1, 2, 3, 4], [1, 2, 3, 4], [1, 2, 3, 4], [1, 2, 3, 4])) # Output: 24
```

10. Next Permutation A permutation of an array of integers is an arrangement of its members into a sequence or linear order. ● For example, for arr = [1,2,3], the following are all the permutations of arr: [1,2,3], [1,3,2], [2, 1, 3], [2, 3, 1], [3,1,2], [3,2,1]. The next permutation of an array of integers is the next lexicographically greater permutation of its integer. More formally, if all the permutations of the array are sorted in one container according to their lexicographical order, then the next permutation of that array is the permutation that follows it in the sorted container. If such arrangement is not possible, the array must be rearranged as the lowest possible order (i.e., sorted in ascending order

```
File Edit Format Run Options Window Help
class TreeNode:
    def init (self, val=0, left=None, right=None):
        self.val = val
        self.left = left
        self.right = right
def bst from preorder (preorder):
    def helper(lower=float('-inf'), upper=float('inf')):
        nonlocal idx
        if idx == len(preorder):
            return None
        val = preorder[idx]
        if val < lower or val > upper:
            return None
        idx += 1
        root = TreeNode(val)
        root.left = helper(lower, val)
        root.right = helper(val, upper)
        return root
    idx = 0
    return helper()
# Function to print tree in inorder (used for testing)
def print inorder (node):
    if node:
        print inorder(node.left)
        print(node.val, end=' ')
        print inorder(node.right)
# Test cases
preorder1 = [8, 5, 1, 7, 10, 12]
preorder2 = [10, 5, 1, 7, 40, 50]
